From Customer Voice to Delivery Execution

FINEXA · MERCHANT EXPERIENCE PRODUCT GROUP · PAYMENTS PILOT · STAKEHOLDERS

1. 2x2 Stakeholder Influence-Interest Mapping

The organization is mapped across classic power and interest quadrants to ensure that system-level technical parameters directly satisfy individual constraints and mitigate delivery risks

Picture 1: Stakeholder Map. Click on the diagram to get to the Stakeholder Directory.

The project's key stakeholders show exceptionally high interest in this project and strong motivation to adopt this AI innovation to eliminate repetitive documentation work and drive evidence-based planning.

Team leadership explicitly recognizes the urgent need for a centralized, automated repository to resolve fragmented workflows and communication lines. This strong cross-functional engagement ensures active, collaborative participation throughout the human-in-the-loop pilot phase to maximize long-term business value.

As the executive champion who launched this initiative, Elena Vance provides critical sponsorship and high enthusiasm for the pilot's potential. Her active advocacy ensures strong strategic backing, as she explicitly relies on this system to establish the auditable data trails and product decision traceability required for high-level roadmap reviews.

2. In-Depth Stakeholder Profiles & Technical System Alignment

Before we begin reviewing individual stakeholder criteria and crossing out specific risk guardrails it is critical to address the foundational philosophy behind the architecture we recommend. Every core operational bottleneck, personal friction point, and systemic hesitation was meticulously analyzed before the final process design was confirmed.

The system is engineered to technically enforce best practices directly within the underlying data layer. By utilising native GSC functions, using deterministic constraints — such as edge tokenization, strict database relationships, taxonomy, and isolated dispatch wrapper — we have built a system that seamlessly guides users toward compliant, seamless execution.

Ultimately, this architecture ensures that the team is structurally aligned to achieve maximum velocity and full auditability without adding a single minute of manual administrative overhead.

Manage Closely (High Power / High Interest)

Elena Vance (Head of Product): Executive Champion

Systemic Frustration: Highly frustrated that product prioritization discussions rely heavily on anecdotal evidence and fragmented spreadsheets. This manual fragmentation makes it impossible to establish a clear, auditable link to verified customer needs during high-stakes roadmap reviews. Elena's main pressure point is time. She operates on a highly limited pilot runway and worries that team adoption friction will delay business value realization.

AI Motivation & Stance: Served as the executive champion who launched the AI pilot initiative. She is highly enthusiastic about reducing low-value manual work, increasing product decision traceability, and driving measurable business value across complex domains.

Hesitation & Risk Guardrails: Main pressure point is execution speed. Elena operates on a highly limited timeline for pilot implementation and worries that adoption challenges across internal teams could slow down the realization of these core benefits.

Technical Architecture Alignment: The insight repository database of raw feedbacks, processed insights, opportunities and jira drafts as a SOT. Elena can generate any Product, Process, or AI operations report instantly through the Appsmith dashboard or via simple, natural-language queries using the /ask_data agent. Absolute traceability to customer data and zero manual reporting effort. Team onboarding isn't assumed — it is monitored and controlled (See. Monitoring Plan).

Priya Patel (Engineering Lead — Merchant Experience)

Systemic Frustration: Distressed that her development team regularly receives incomplete Jira tickets and loosely defined requirements. This directly triggers constant, wasteful clarification loops, engineering rework, and severely delayed delivery cycles.

AI Motivation & Stance: Highly skeptical of the AI rollout. Priya fears that product managers will use the automated tools to rapidly flood her engineering backlog with inaccurate, unverified, or incomplete AI-generated user stories. She is structurally resistant to a general overreliance on these outputs without deep human critical thinking.

Strict Non-Negotiable Demand: Priya will actively resist the tool's adoption unless strict, non-negotiable human review checkpoints are permanently established before *any* candidate Jira ticket is pushed to engineering pipelines.

Technical Architecture Alignment: Handled by the deterministic Jira Wrapper API isolation boundary. The automated system lacks deployment credentials and cannot bypass human evaluation. Gate 3 forces a mandatory draft layout validation and manual story-point configuration by engineering, ensuring zero backlog flooding.

Marcus Bauer (Senior Product Manager)

Systemic Frustration: Exhausted by spending hours manually reading, summarizing, and tagging themes across dozens of merchant interview transcripts and support tickets instead of doing strategic product work.

AI Motivation & Stance: Positioned as an eager early adopter. Marcus is keen to use reusable AI commands to automate tedious documentation and speed up the turnaround from discovery to backlog readiness.

Hesitation & Risk Guardrails: Quietly worries about overreliance on generated outputs. Marcus requires firm reassurance that the AI will act strictly as an assistant rather than replacing his ultimate product decision authority.

Technical Architecture Alignment: Handled via the Appsmith Operational UI Hub. The interface streamlines documentation tasks while maintaining manual override dropdown controls across Gates 1 and 2. To prevent automation complacency, the text layout splits descriptions into a rigid Known (Fact + Direct Text Citation) vs Assumptions (Model Interpretations) system, ensuring Marcus remains the absolute decision authority.

Keep Satisfied (High Power / Medium Interest)

Simone Dubois (Risk and Compliance Manager)

- **Systemic Frustration:** Strained by current inconsistent handoffs between product discovery and delivery, which makes verifying that strict compliance and risk guidelines are met an uphill battle.
- **AI Motivation & Stance:** Represents the strongest layer of organizational resistance due to the strict guardrails surrounding regulated financial data handling. Simone is deeply concerned about financial data privacy, confidentiality leakage, and the potential for structural bias in AI-driven prioritization algorithms.
- **Strict Non-Negotiable Demand:** Simone will block the pilot entirely if she detects a lack of data security controls. She demands that all AI outputs remain fully auditable, secure, and reliable, with a clear human-in-the-loop validation process.

Technical Architecture Alignment: Addressed through the **Google Cloud DLP Pipeline**. Financial details and customer PII are tokenized at the ingestion point. The system relies on Legitimate Interest for feedback analysis (pending sign-off), and enforces strict **BetrVG §87** compliance by recording reviewer interactions in `gate_decisions` solely by functional corporate role. Handoff between discovery and delivery is the opportunity status change, done by PM - Marcus, when he confirms the opportunity is ready for drafting.

Keep Informed (Medium-Low Power / High Interest)

Liam O'Connor (Customer Support Operations Manager)

Systemic Frustration: Deeply frustrated that despite passing along 100+ support tickets and operational escalations regarding merchants' confusion over payment and balance statuses, these insights remain completely trapped in separate tools and disconnected from the actual product backlog.

AI Motivation & Stance: Highly optimistic about the feedback-logging step. Liam believes it could create a centralized, searchable customer insights repository that finally gives his support tickets a permanent, visible influence in the core product lifecycle.

Hesitation & Risk Guardrails: More resistant when it comes to using AI for the final prioritization of opportunities. He fears the system might suffer from synthesis bias, inadvertently deprioritizing crucial operational escalations in favor of purely feature-driven requests.

Technical Architecture Alignment: Addressed by the system `regression_flag` and `last_insight_at` markers. When incoming customer feedback maps dynamically to a pre-existing opportunity previously marked as resolved in Jira, the system triggers a regression warning. This forces the issue back into the active review queue, ensuring operational escalations maintain visibility and cannot be quietly buried by features.

3. Project Scope & RACI Accountability Matrix

To establish operational clarity before project handover, the pilot provides an interactive **RACI Governance Hub** directly within the deployment dashboard. This interface functions as a live accountability registry where internal team members can filter by their individual name profiles.

Picture 2: Project RACI Matrix. Click on the diagram and choose second tab to get more information.

Qualifications-Based Accountability Distribution and Process Ownership

Accountability (A) across the 12 core pipeline components has been evenly balanced and assigned to the leadership group. This mapping guarantees that process ownership matches individual technical qualifications and project interests:

- **Elena Vance (Head of Product):** Governs high-level strategic alignment, business target measurements, and value tracking views
- **Marcus Bauer (Senior PM):** Directs daily interface touchpoints, user journey reviews, and administrative automation features
- **Priya Patel (Engineering Lead):** Safeguards backend engineering pipelines, database schemas, and integration access controls
- **Simone Dubois (Risk & Compliance):** Controls the deterministic data sanitization pipeline and system action logging configurations
- **Liam O'Connor (Support Ops Manager):** Manages cross-channel incoming feedback conduits to protect customer escalation pathways

Assigning ownership at the outset keeps these owners in the loop throughout the build, so the transition to steady-state operation carries no knowledge gap — they have been accountable for their component from the beginning, not handed it at the end.
